**Abstract.** This paper describes the SEU-RedSun rescue robot team, which will participate RoboCup 2011. We have two robots, One robot is four-wheel independent driving construction, which is easy over the incline and low step terrain, and is easy to control. It focuses on implement the autonomous function. The other is a tracked robot with four flippers; it excels on rough terrain with tele-operation. Both robots are able to create map automatically, and share the information each other. We have made considerable improvements since the Robocup 2010 and we are still improving.

### **Introduction**

SEU-RedSun rescue robot team was found in 2008, participated in China Open 2009, China Open 2010 and RoboCup 2010 Singapore, original from virtual robot competition SEU-RedSun team, which won the champion in RoboCup 2010 Singapore and RoboCup 2008 Suzhou, China and was awarded 2<sup>nd</sup> place in RoboCup 2009 Graz, Austria.

Fig 1 shows our robots: the Top one is the first version made by our team which awarded 2<sup>nd</sup> place in China Open 2009; the left one below is our second version which got 2<sup>nd</sup> place in China Open 2010 and participated in Robocup 2010 Singapore, the right one below is the autonomous robot with four-wheel independent driving construction which also participated in China Open 2010 and Robocup 2010 Singapore.

## 2. Operator Station Set-up and Break-Down (10 minutes)

We use only one notebook PC for the operation, so our main devices are only one robot and one notebook PC, therefore the operation is plug and play and the Set-up and Break-Down operation will be quick in a similar way.

## 3. Communications

The robots are configured with wireless network with 802.11a/5GHz. Both robots only use one wireless communication channel. We use dual band router and miniPCI wireless board(See Fig.2). Considering the reliability of wireless communication in practice, we reduce the dependence on wireless, the autonomous robot can normally run in drop out zone because of fully on board data process control, the tele-operative robot can work in reduced functionality mode.

Fig.2 dual band router and miniPCI wireless board

Table 2. Communication channels

Rescue Robot League		
SEU-RedSun (CHINA)		
MODIFY TABLE TO NOTE <u>ALL</u> FREQUENCIES THAT APPLY TO YOUR TEAM		
Frequency	Channel/Band	Power (mW)
5.0 GHz - 802.11a	1 channel/Selectable	100

## 4. Control Method and Human-Robot Interface

According to the different functionality, each robot use independently control method. On the autonomous robot, we use MCU + Notebook PC construction. About the tele-operative robot, we use arm9 as the core processor in our first version of the tele-operative robot. Taking into account the scalability and flexibility, we use

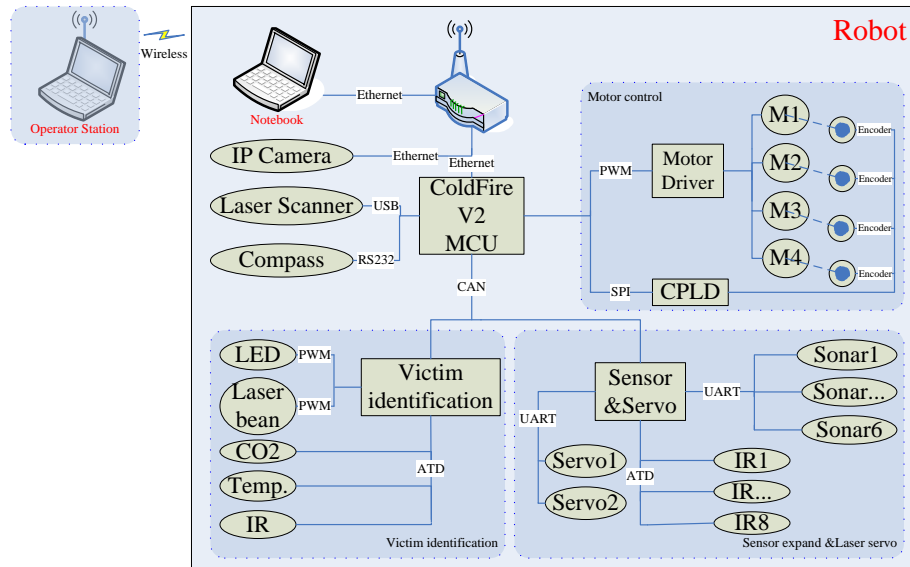

PC/104+ construction to control the flexible mechanism. Meanwhile it is easy to update step by step, because each module is independent, the common function control module, such as CO<sub>2</sub>, temperature, laser 2-degree servo module, can work on both robot platforms by no modification due to use CAN bus.(See Fig.3)

**Fig.3 two robots control**

#### **4.1 Autonomous robot**

Fig.4 describes the autonomous robot construction. The robot is equipped with notebook, the ColdFire MCU (the main controller on the robot for robot motion control), sensor data acquirement (including laser scanner, electronic compass, CO<sub>2</sub>, temperature, sonar and IR distance sensor). For decode the rotate encoder pulse, one CPLD is used. The video and audio stream is obtained by PTZ IP camera, and direct transmits to notebook through Ethernet. The operator station is option as a remote monitor.

**Fig. 4 Diagram of the autonomous robot control hardware structure**

#### 4.2 Tele-operative robot

In the first version, we use ARM as the main controller on the robot (Fig.5) , this way can obtain compact construction and we can design a system as we want. And it works well as we expect. But it is difficult to update step by step because of system integrated on the single board. Of course, we found it is difficult to compress video and process on the ARM processor.

**Fig. 5 The control box on the old robot**

On the second version, we use PC/104+ embedded PC as the main control on the robot(Fig.6), as a common local bus standard, it is easy to implement each function independently, meanwhile, for enough performance of CPU, the robot can run in

drop-out zone with reduced function. Because we found the wireless communication is not always stable.

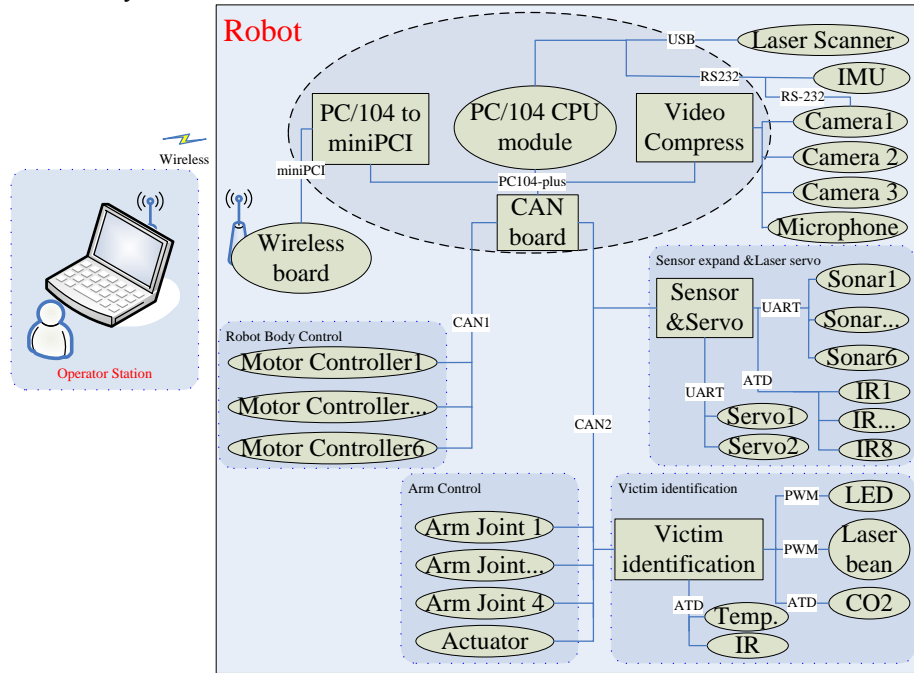

Fig. 6 Diagram of the tele-operative robot control hardware structure

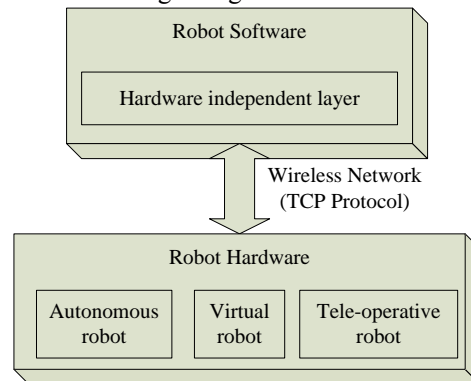

Fig. 7 Embedded computer and camera on tele-operative robot

#### 4.3 Autonomous and Human-Robot Interface

There are some effective ways on localization, navigation, and multi-robot co-operation, which are tested in the simulation environment. We focus on complement this way on our real robot, meanwhile, find the different between real world and the simulation environment in detail (the unconfirmed factor is more than the simulation environment). However, in the early phase, it is effective to use UARSim to develop the software framework and new method first test, and it is not enough to test the

method which used on the real robot, so in the new vision, we still use UARSim in the early phase to develop the software when the hardware of the robot is in update, so in the framework of the software, there is a hardware-independent layer, to reduce the effect about different hardware framework, which is shown on Fig.8. The flow chart of the software is shown on Fig.9. Fig.10 shows the GUI of robot control.

**Fig. 8 The control method of software**

**Fig. 9 Flow chart of robot control software**

**Fig. 10 GUI of robot control**

## 5. Map generation/printing

To achieve an accurate geo-referenced map, the robot should know its position synchronously and exactly during the exploration, while the position data got from the odometry sensor or inertial navigation sensor is always with a large error. Laser range scanners can deliver highly accurate measurements, and a position estimated based on scan matching is impressive for indoor environments. Fig.11 shows the map in China Open 2009.

**Fig. 11 The map in Robocup China OPEN 2010**

## **6. Sensors for Navigation and Localization**

In order to manipulate the robot in an unknown environment, we use several digital sensors to gather information about the environment. The robot is equipped with the following sensors for localization and navigation:

1. Scanning Laser Range Finder (URG-04LX) is used to provide a precise measurement <sup>[4]</sup>.
2. Digital Compass Module (HMR 3300) measures the roll, pitch and heading direction of the robot <sup>[5]</sup>.
3. Digital Compass Module (OS5000S) is same to HMR3300, but the output data frequency is configurable, it is easy to sync to other sensor output.
4. MTi xsens AHRS, it is good in dynamical on measuring the roll, pitch and heading.
5. Odometry, it use the rotate output to compute the head and distance. It is worth in the skipped environment, but it one option to help localization and navigation.

The sensors are shown in Fig.12.

**Fig. 12 Scanning Laser Range Finder & Digital Compass & IMU**

## 7. Sensors for Victim Identification

We use a camera fixed on the arm of the robot for identifying and localizing victims. The video streams with picture data are transferred into the operator interface. Furthermore, the microphone, temperature and CO<sub>2</sub> sensors are equipped on the end of the robot arm to gain more information for victim identification.

Fig. 13 CO<sub>2</sub> & Temperature module

## 8. Robot Locomotion

The robot is the same as shown in the Fig 14. The drive system of the robot use conveyer belt which can be used on different types of terrain. This robot includes several parts: two movement modules for the left and right and two pairs of flipper (front and back). Each pair of flipper can rotated 360 degree and work independently of each other. Through compare and research, we find that this structure is better for the disaster situation.

In order to step up the bottom of the body, the body and movement module are entirely separated except several linkers. Therefore, three DC motors are hided in the body of movement module, one for the movement of belt and the others for the rotation of flippers. Most of the structure is made of Aluminum and the belt is made of synthetic rubber.

Fig. 14 Tele-operative robot

## 9. Other Mechanisms

Modular design approach is used for the robot. In that way, the robot can be divided into several modules, left and right main track modules, two pair of flipper, body control section and mechanical hand. Every module can be easy removal and assembly. When a certain part comes across with a problem, we can quickly get to replace the module in a short time, so the robot can play a greater rescue effect.

## 10. Team Training for Operation (Human Factors)

The operator should be familiar with the structure and the function of the GUI and be able to immediately understand the data of all sensors showed in the GUI. As the operator, he also needs to drive the robot remotely according to the video stream of the camera and the distance of the obstacles scanned by laser.

## 11. Possibility for Practical Application to Real Disaster Site

We yet have no practical experience with real disaster sites. However, we consider the practical application when design the robot, such as compact mechanism, modular design, less operator station setup time.

## 12. System Cost

**Table 2.** autonomous robot cost

Part Name	Quantity	Price
motor + Gearhead + Encoder	4	¥3,000
Other mechanical parts and manufacture		¥3,000
Scanning Laser Range Finder(URG-04LX)	1	¥19,000
Digital Compass Module (OS5000S)	1	¥3,000
Wireless router (DIR-628)	1	¥1,000
Laptop	2	¥30,000
Laser servo controller	2	¥2,000
IP Camera(FSC1010)	1	¥2,800
PCB		¥2,000
Other electrical parts		¥2,000
Battery	2	¥1,000
<b>Total</b>		¥68,800

**Table 2.** tele-operative robot cost

Part Name	Quantity	Price
Maxon motor (RE36) + Gearhead + Encoder	4	¥36,000

Maxon motor (RE40) + Gearhead + Encoder	2	¥20,000
Other mechanical parts and manufacture		¥60,000
PC104-plus computer	1	¥15,000
Scanning Laser Range Finder(URG-04LX)	1	¥19,000
MTi AHRS (MTi-28 A53 G35)	1	¥18,000
Laptop	1	¥15,000
Camera	3	¥5,000
Laser servo controller	2	¥2,000
PCB		¥3,000
Other electrical parts		¥5,000
Battery	2	¥4,000
<b>Total</b>		<b>¥202,000</b>

### 13. Lessons Learned

We never stop improving and perfecting our robot. We will be continue to improve the second edition of the robot, and with the same time our new version of the robot's design is in progress. In our new robot, we have carried out many changes in the mechanical structure. It will be more lighter, more flexible and be more powerful obstacle. We will do our best to prepare this year's competition.
